Footprinting with Maltego: networkwalks.com

Nov 8, 2026 · @sheila

Maltego Graph 4.14.0 (free plan) found two email addresses linked to networkwalks.com: one organisational address and one registrar contact.

Objective and scope

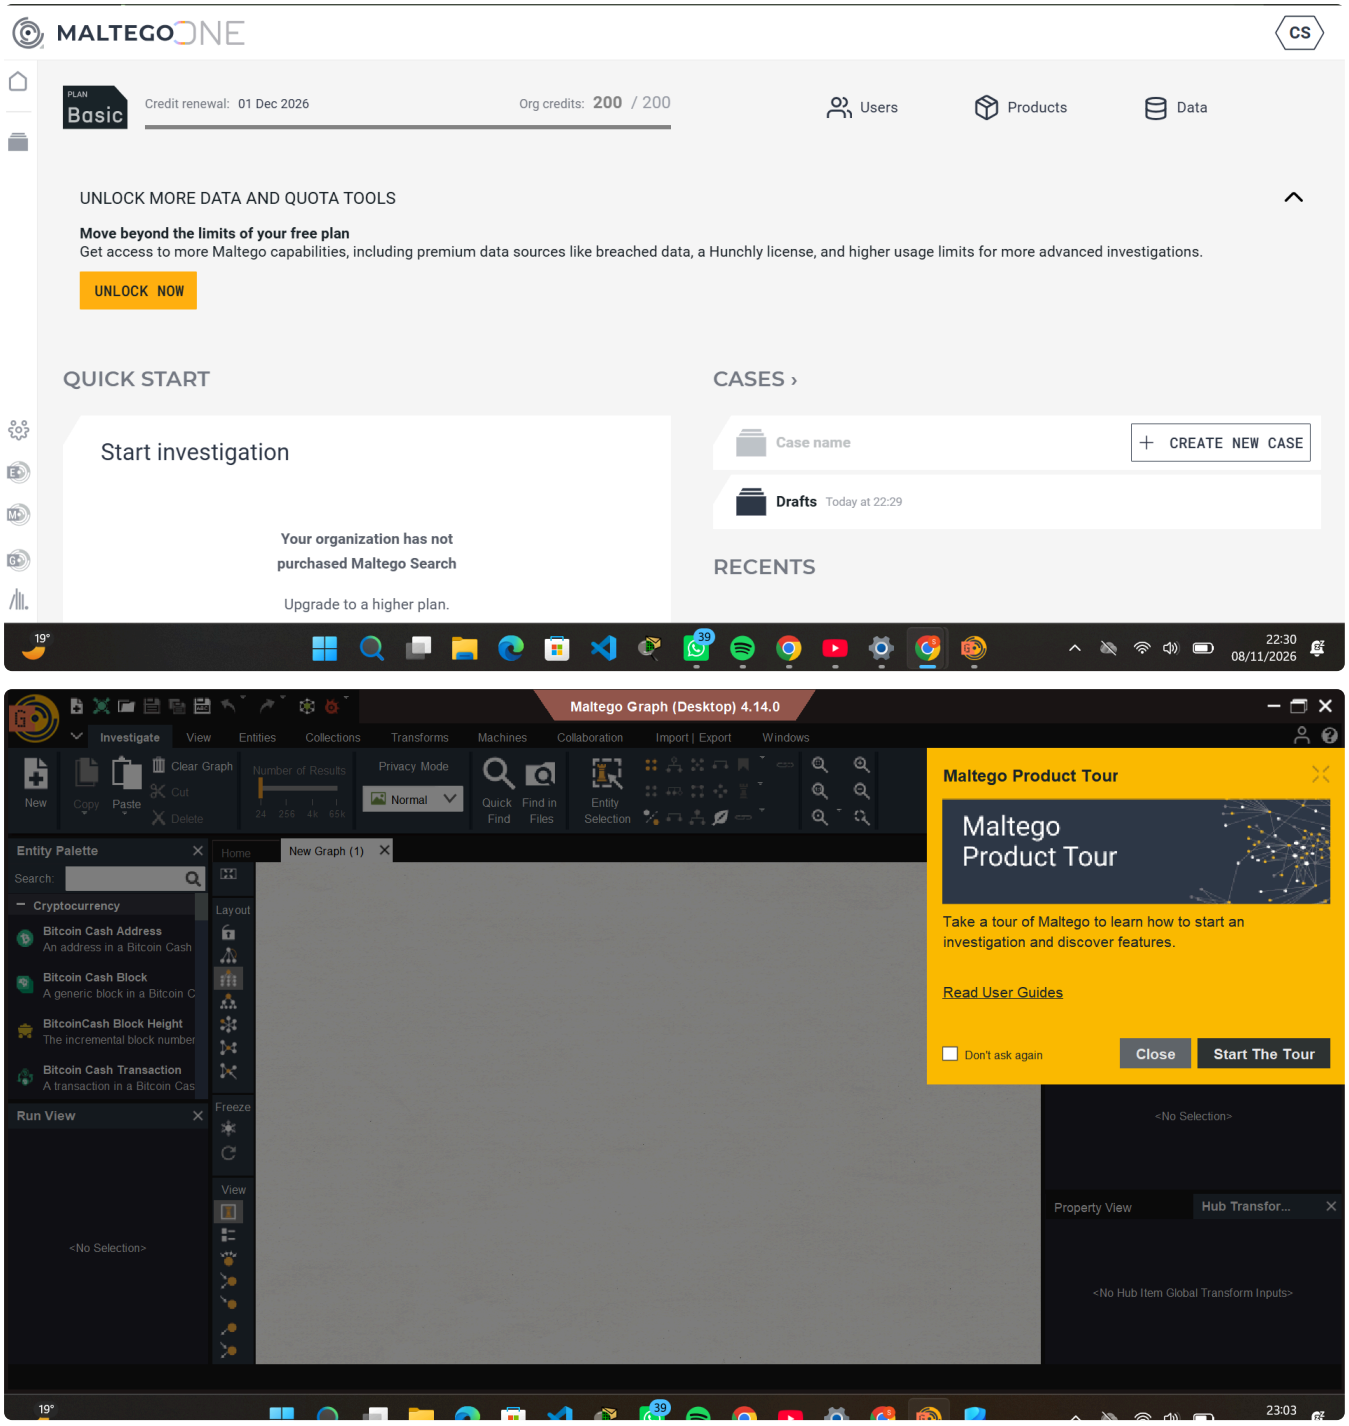

The task is to install Maltego and find email addresses linked to the target domain networkwalks.com. The domain is the assigned target of this course project (W2-PM3), tested with due permission. Only passive, public-source transforms were run, and nothing was accessed or changed on the target.

Task 1: Install and activate Maltego

Maltego Graph (Desktop) 4.14.0 was installed on Windows and activated with a free Maltego ID on the Basic plan (200 credits, renewing 1 December 2026).

1. Downloaded Maltego Graph for Windows and ran the installer as administrator.
2. Launched Maltego, chose Maltego ID with Online Activation, and accepted the licence.
3. Created a Maltego ID and logged in through the browser.
4. Selected the **Utilities** data source, kept the default browser and Privacy Mode **Normal**, then opened a blank graph.

Figure 1 shows the Maltego One dashboard with the Basic plan, and Figure 2 shows the blank graph in Maltego 4.14.0.

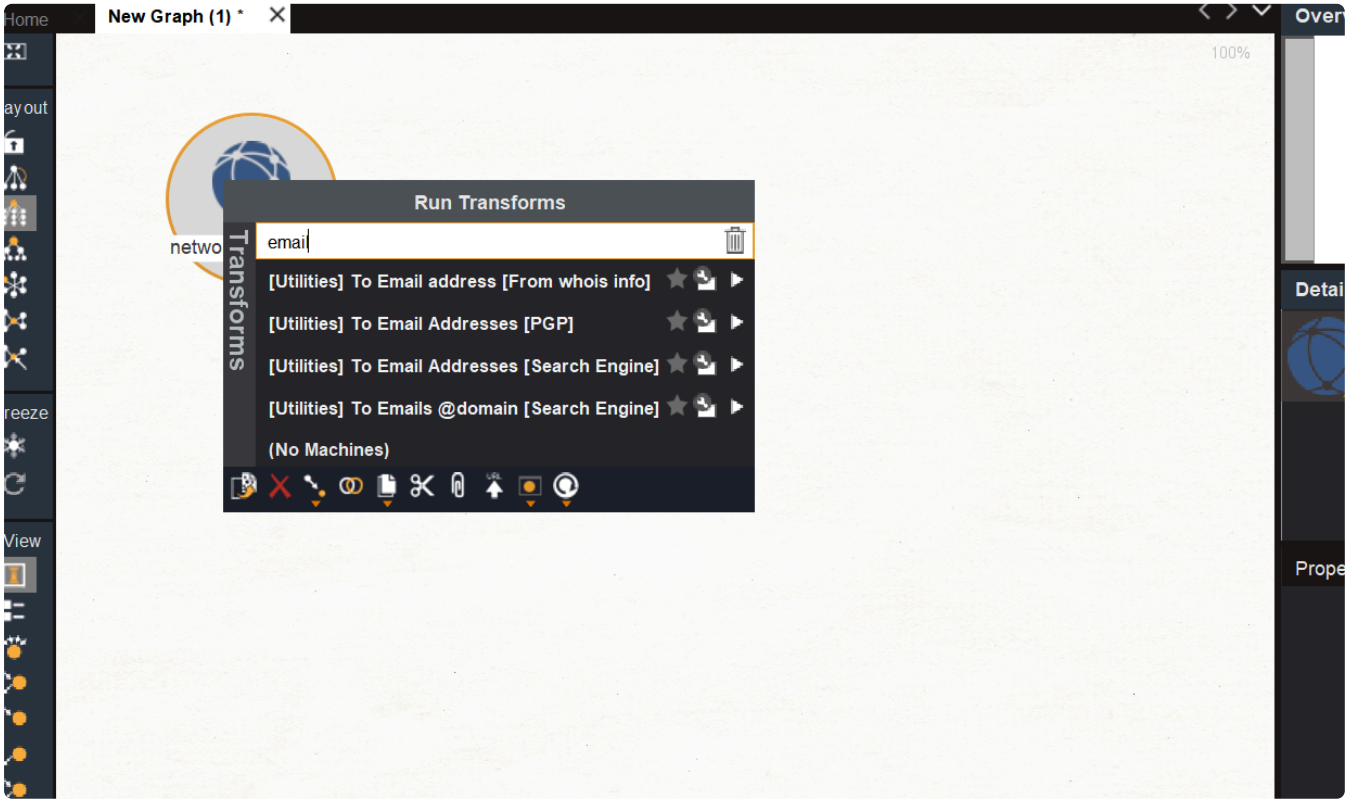

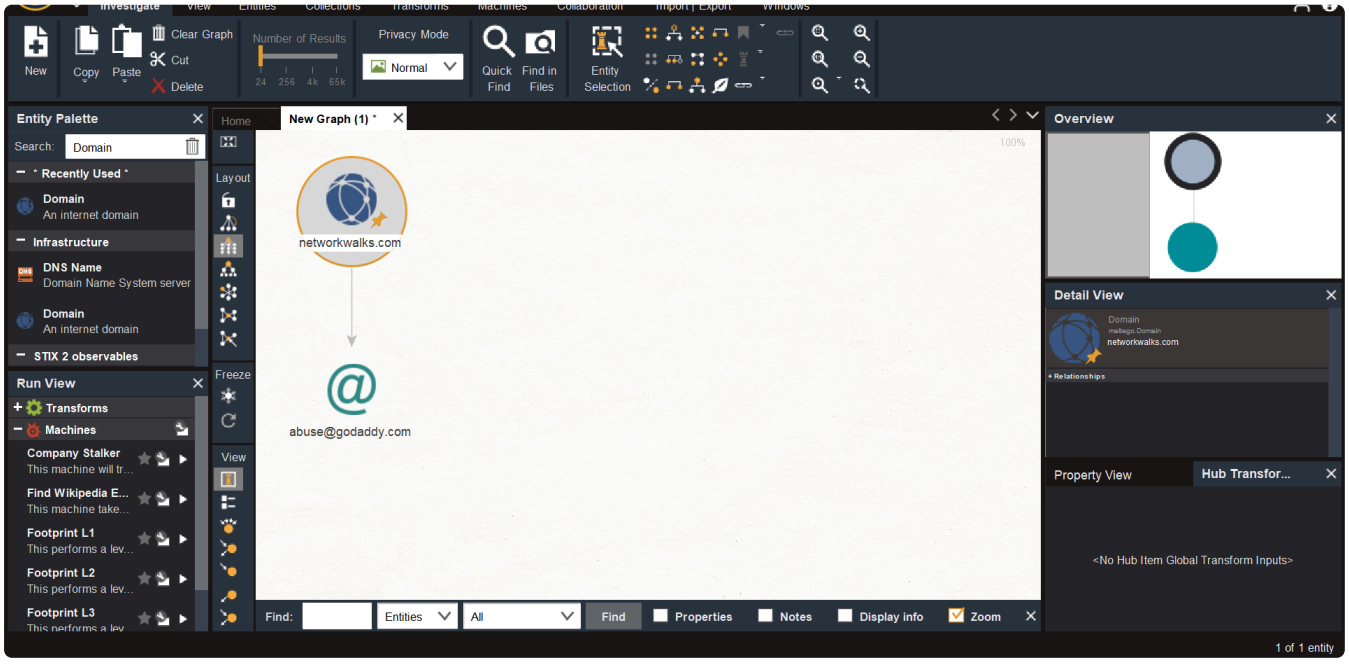

Task 2: Find email addresses

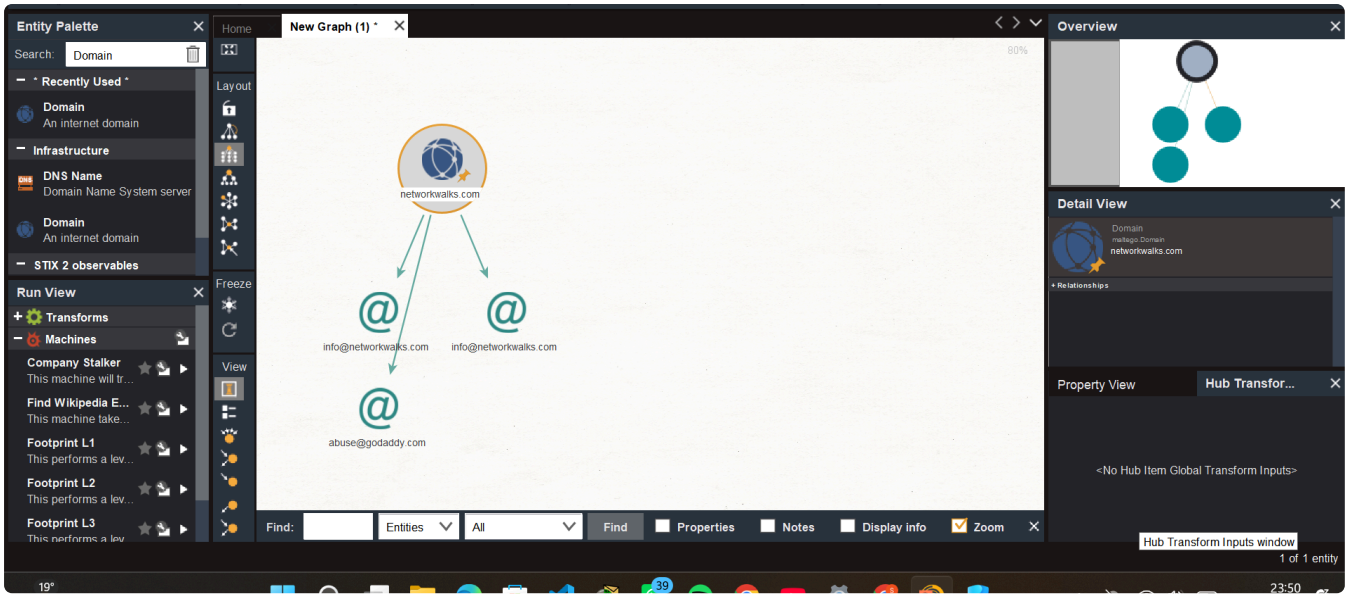

A **Domain** entity was added to the graph and renamed to networkwalks.com. Three transforms from the Utilities source were then run on it, one at a time:

1. To Email address [From whois info]
2. To Email Addresses [Search Engine]
3. To Emails @domain [Search Engine]

Each new email appeared as an entity linked to the domain. The final graph shows info@networkwalks.com (returned by both search-engine transforms, so drawn twice) and abuse@godaddy.com.

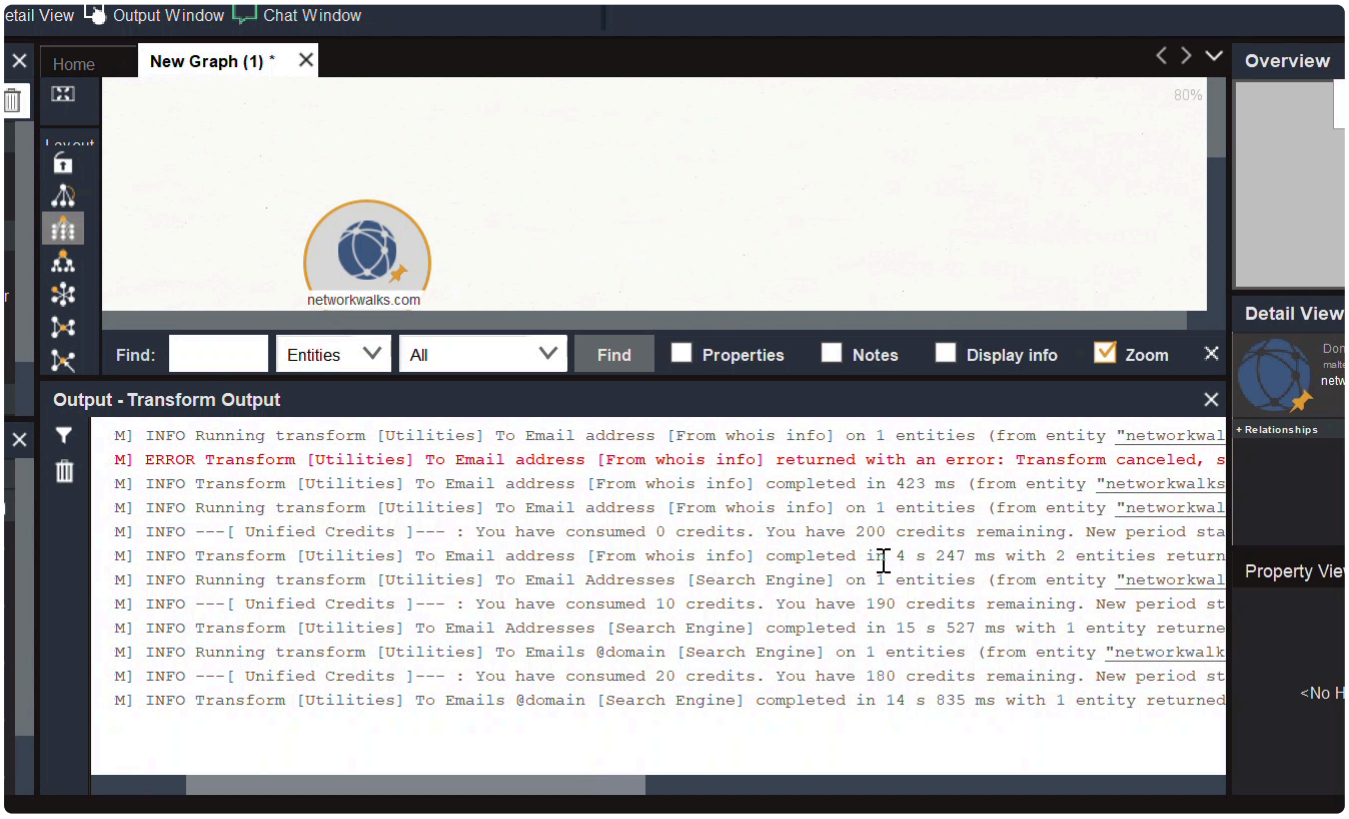

Troubleshooting: first WHOIS run failed

The first run of To Email address [From whois info] returned an error in the Output window: "Transform canceled, server not trusted". It was re-run on the same domain and completed in 4 s 247 ms with 2 entities returned. The same connection problem had earlier stopped the login wizard ("Login link cannot be generated"). It cleared before the transforms were re-run.

Findings

Email	Source transform	Belongs to
info@networkwalks.com	To Email Addresses [Search Engine]; To Emails @domain [Search Engine]	Target organisation (generic contact)
abuse@godaddy.com	To Email address [From whois info]	Domain registrar (GoDaddy), not the target

The three transforms used 20 of 200 credits (10 each for the two search-engine runs), leaving 180.

Risk and mitigation

Public addresses such as info@ can be used for phishing and to guess staff email formats, and WHOIS data reveals the registrar. To reduce exposure, use WHOIS privacy, role-based mailboxes, email filtering such as SPF, DKIM and DMARC, and staff awareness training.
